*Fulbourn Hospital, Fulbourn, Cambridge*

# Emotions: a Doomsday device?

*Kubrick (1964) 'Dr Strangelove'*

51-2202

## Convincing others that you're not rational

---

*Kubrick (1980) 'The Shining'*

# Autonomic changes are hard to fake

# Theories about the evolution of emotions

---

Aggression

Submission

*Darwin (1872)*

## Measuring emotions

---

*Emotions have several components; all can be measured.*

- *subjective*
- *behavioural*
- *physiological*

*Subjective components cannot be measured in animals, but clever behavioural techniques can still give us clues to their internal mental state.*

# Universal facial expressions: innate, primary emotions?

---

*Ekman et al. (1972); Ekman & Friesen (1975)*

# *Theories of emotion*

## The James–Lange theory of emotion (1)

---

*Common sense says, we lose our fortune, are sorry and weep; we meet a bear, are frightened and run; we are insulted by a rival, are angry and strike.*

*The hypothesis here to be defended says that this order of sequence is incorrect... [instead] we feel sorry because we cry, angry because we strike, afraid because we tremble...*

*Without the bodily states following on the perception, the latter would be purely cognitive in form, pale, colourless, destitute of emotional warmth. We might then see the bear, and judge it best to run, receive the insult and deem it right to strike, but we could not actually feel afraid or angry.*

# The James–Lange theory of emotion (2)

---

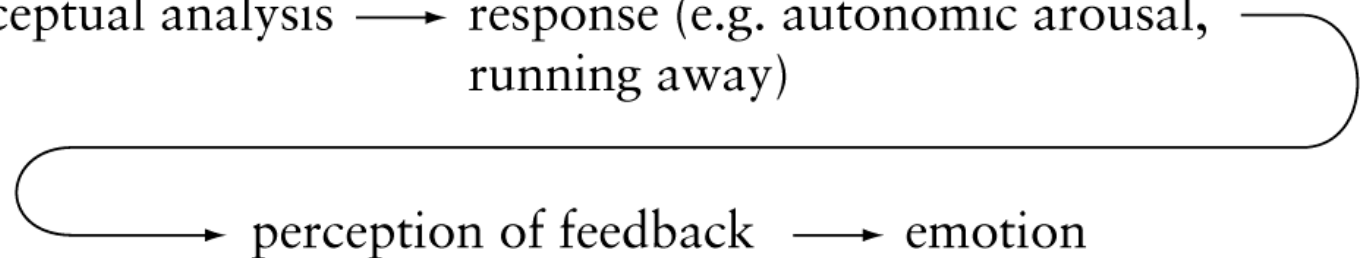

## *Traditional view*

event → perceptual analysis → emotion → response

## *James–Lange*

event → perceptual analysis → response (e.g. autonomic arousal, running away)

perception of feedback → emotion

*James (1884); Lange (1885)*

# The Cannon–Bard theory of emotion

---

Objected to James–Lange theory on five grounds:

1. **separation of viscera from CNS** did not impair ‘emotional’ responses in animals (Sherrington, Cannon);
2. the same visceral changes occur in **different emotional states**;
3. the viscera are relatively **insensitive** (e.g. to surgery);
4. visceral changes are **too slow** to account for emotions (some affective reactions over in 0.8s; many autonomic responses slower);
5. **artificial induction** of visceral changes does not induce emotional experience (Marañón, adrenaline injection).

# Subjective feelings following spinal cord lesions

*“It’s a sort of cold anger. Sometimes I act angry when I see some injustice. I yell and cuss and raise hell, because if you don’t do it sometimes, people will take advantage of you. But it just doesn’t have the heat to it that it used to have. It’s a mental kind of anger.”*

## Visceral changes distinguish emotions (1)

---

*Subjects participated in a fictitious experiment on hypertension and were*

*(1) given electric shocks ('faulty apparatus') → **fear***

*(2) insulted by a 'technician' → **anger***

# Visceral changes distinguish emotions (2)

Fig. 1. The variables recorded in this study. The Grass eight-channel electroencephalograph was used as the main recorder and amplifier. Since the Grass has only A. C. amplifiers, modulated A. C. envelopes were used for all continuous variables.

*Note also speed of skin conductance change (in general, this can be quite fast).*

# Visceral changes distinguish emotions (3)

Fig. 2. The polygraph reactions, in standard score units, to the two stress situations called "anger" and "fear."

*Anger and fear differentiated by change in diastolic blood pressure, heart rate, skin conductance changes, muscle tension, respiratory rate...*

# Autonomic responses to relived emotions/ facial expression (1)

*Professional actors asked to*

*(1) relive emotions;*

*(2) create emotional expressions step-by-step*

Fig. 1. Frames from the videotape of one of the actor's performance of the fear prototype instructions: (A) "raise your brows and pull them together," (B) "now raise your upper eyelids," (C) "now also stretch your lips horizontally, back toward your ears."

# Autonomic responses to relived emotions/ facial expression (2)

Fig. 2. Decision tree for discriminating emotions in direction facial action task.

*e.g. anger and fear both increase heart rate; anger (but not fear) causes an increase in finger temperature (peripheral vasodilation)*

## Emotional interpretation of peripheral feedback

---

*Naïve subjects asked to move muscle groups one by one (for a 'facial muscle experiment').*

*Occasionally, they made smiles or frowns, without (apparently) being aware of this.*

*They described themselves as happier whilst smiling, angrier whilst frowning, etc.*

*They also rated cartoons they'd seen while smiling as being funnier.*

**Note:** *autonomic as well as skeletal muscle feedback?  
(Ekman, previous slide.)*

# Schachter's cognitive labelling theory of emotion

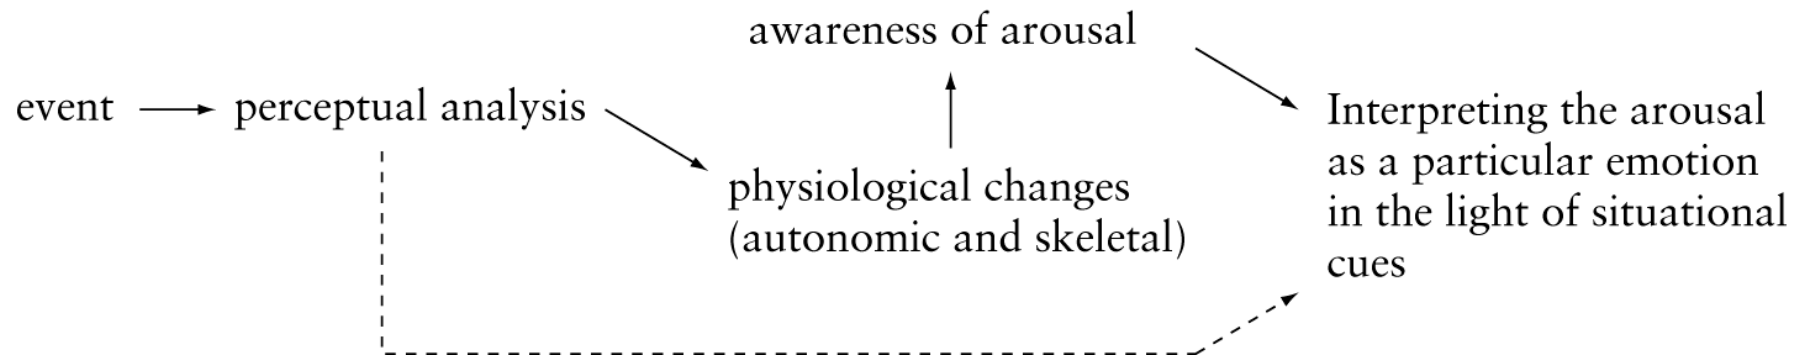

---

Suggested that

- emotional experience *does* depend on bodily changes;
- physiological changes precede emotion;
- bodily changes are *not solely* responsible for emotion;
- arousal must be *interpreted*.

Two-factor theory (arousal + interpretation).

*Schachter*

*Schachter (1964)*

# Unlabelled arousal can become euphoria or anger

---

## *Drug condition:*

- *Epinephrine informed (arousal, but attributed)*
- *Epinephrine ignorant (unattributed arousal)*
- *Epinephrine misinformed (unattributed arousal)*
- *Placebo*

## *Interaction with stooge:*

- *Euphoria*
- *Anger*

<i>Self-report results (higher scores indicate greater euphoria; lower scores indicate anger).</i>	Group	Condition	
		Euphoric stooge	Angry stooge
	Epi informed	0.98	1.91
	Epi ignorant	1.78	1.39
	Epi misinformed	1.90	<i>not performed</i>
	Placebo	1.61	1.63

## Motivated behaviour: an overview

---

- Reinforcement **must be defined carefully to avoid circular arguments.** Theories (Skinner, Hull, Premack, Timberlake). Motivational states are internal 'hidden' variables that help to explain behaviour.
- Apparently goal-directed behaviour is complex; several representations / processes contribute. For example, rats pressing levers encode
  - **the** instrumental (action–outcome) contingency;
  - **the** value of the outcome as an instrumental goal;
  - **the (dissociable)** 'hedonic' value of the outcome;
  - **direct** stimulus–response 'habits';
- ... and is influenced by Pavlovian processes including conditioned reinforcement **and** Pavlovian–instrumental transfer.
- Motivational state affects several of these processes.
- Once your goals have been obtained, consummatory behaviour takes over; this is organized by the **hypothalamus**.
